Chapter 12 Nutrition and Energy for Life

Chapter Objectives:
- Learn about macronutrients (carbohydrates, lipids, proteins) and micronutrients (vitamins, minerals).
- Learn about metabolism and energy production, and the basic process involved in the catabolism of food.
- Learn how ATP is used in energy storage and the role of mitochondria in metabolism.
- Learn about the coenzymes in the common catabolic pathway (Coenzyme A, NAD, FAD).

Angelo State University
CHEM 2353 Fundamentals of Organic Chemistry
Organic and Biochemistry for Today (Seager & Slabaugh)
www.angelo.edu/faculty/kboudrea

Nutritional Requirements

- The science of nutrition focuses on the study of food, water, and other nutrients and the ways in which they are used by living organisms.
- Nutrients are necessary for the body to function and remain healthy.
  - Macronutrients are needed in large amounts (gram quantities) because they provide energy and materials required to build and repair tissues.
    - carbohydrates, proteins, and lipids
  - Micronutrients are required in small amounts (milligram or microgram quantities). Many of these are used in enzymes.
    - vitamins and minerals
Nutritional Requirements

• In addition to nutrients, the body also requires water and fiber.
  – **Water** — 45-75% of human body mass is water.
  – **Fiber** is an indigestible plant material made mostly of cellulose. It helps to maintain digestive health by providing roughage to stimulate contraction of the intestines and help pass food through the digestive system.

• The **Daily Values (DV)** are a set of nutritional guidelines established by the FDA for use on food labels:
  – **Reference Daily Intakes (RDI)** — proteins and 19 vitamins and minerals
  – **Daily Reference Values (DRV)** — other nutrients and food components

![Daily Values (DV)](image-url)
Macronutrients: Carbohydrates, Lipids, and Proteins

Carbohydrates

- Carbohydrates provide energy for body functions and useful materials for the synthesis of cell and tissue components.
- **Simple carbohydrates** are the monosaccharides and disaccharides such as glucose, fructose, sucrose, etc.
- **Complex carbohydrates** are the polysaccharides amylose and amylopectin (starch).
  - Cellulose is also a complex carbohydrate, but it serves a nonnutritive role as fiber.
- Current recommendations are that about 58% of our daily calories should come from carbohydrates; currently, about 46% of the typical American diet comes from carbohydrates, and much of that comes from simple sugars rather than from complex carbohydrates.
**Lipids**

- About 95% of the lipids in foods and in our bodies is in the form of triglycerides. The fatty acids in the triglycerides can be either *saturated* or *unsaturated*.
  - Triglycerides containing a high concentration of unsaturated fatty acids are liquids at room temperature (oils).
  - Triglycerides containing a high concentration of saturated fatty acids are solids at room temperature (fats).
- Lipids provide a concentrated source of energy.
  - lipids: 9 Cal/g
  - proteins and carbohydrates: 4 Cal/g
- Lipids contain some fat-soluble vitamins and help to carry them through the body.
Lipids

- Lipids improve the texture of foods, absorb and retain flavors, and are digested more slowly than other foods, prolong the feeling of satiety (satisfaction and fullness after a meal).

- Linoleic and linolenic acids are essential fatty acids because they cannot be synthesized in the body, and must be obtained from the diet.
  - Corn, cottonseed, soybean oils, and wheat germ are good sources for these acids.

- The average American receives about 42% of the calories in their diets from fat, while the recommendation is about 30%.

Fatty Acid Composition of Common Food Fats
**Proteins**

- The RDI for proteins varies for different groups of people.
- Protein is necessary for:
  - production of new tissue
  - maintenance and repair of cells
  - production of enzymes, hormones, and other important nitrogen-containing compounds
- Proteins provide 4 Cal/g of energy.

**Proteins**

- On digestion, proteins are broken down into amino acids, which are then absorbed into the body’s amino acid pool.
  - Several amino acids are *essential*, and must be obtained from the diet.
- **Complete proteins** contain all of the essential amino acids in the proportions needed by the body.
Micronutrients I: Vitamins

Vitamins

- **Vitamins** are organic micronutrients that the body cannot produce in amounts needed for good health.
- Some vitamins are highly polar, and are **water-soluble**.
  - With the exception of Vitamin C, water-soluble vitamins function as *coenzymes*.
  - Excess amounts of water-soluble vitamins are usually removed by the kidneys.
- Vitamins with nonpolar molecule structure dissolve only in nonpolar solvents, and are **fat-soluble**.
  - Care must be taken to avoid overdoses of the fat-soluble vitamins, since they are not eliminated as readily. (They are stored in the liver and fatty tissues.)

Chapter 12 Nutrition and Energy for Life

Water-Soluble Vitamins

Vitamin B₁ (thiamine)
Thiamine pyrophosphate is a coenzyme in the catabolism of sugars and amino acids. All living organisms use thiamine, but it is only synthesized in bacteria, fungi, and plants; deficiency results in beriberi.

Vitamin B₂ (riboflavin)
Central component of the cofactors FAD and FMN, and is used in all flavoproteins; repairs damage due to oxidative stress, and is involved in photosynthesis, DNA repair, and apoptosis.

Vitamin B₃ (niacin, nicotinic acid)
Forms part of the coenzyme NAD⁺ (nicotinamide adenine dinucleotide); involved in DNA repair and the production of steroid hormones in the adrenal gland.

Vitamin B₅ (pantothenic acid)
Required for the synthesis of coenzyme-A; needed in the synthesis and metabolism of proteins, carbohydrates, and fats.

Vitamin B₆ (pyridoxine, pyridoxal phosphate)
A cofactor in many reactions in amino acid metabolism; necessary for the enzymatic reaction governing the release of glucose from glycogen.

Vitamin B₇ (biotin)
A coenzyme in the metabolism of fatty acids and some amino acids, and plays a role in gluconeogenesis.

Vitamin B₉ (folic acid)
A cofactor in methyl group transfers; needed to synthesize and repair DNA; also important in aiding rapid cell division and growth, and producing healthy red blood cells (and preventing anemia).

Water-Soluble Vitamins

Vitamin B₁ (thiamine)
Thiamine pyrophosphate is a coenzyme in the catabolism of sugars and amino acids. All living organisms use thiamine, but it is only synthesized in bacteria, fungi, and plants; deficiency results in beriberi.

Vitamin B₂ (riboflavin)
Central component of the cofactors FAD and FMN, and is used in all flavoproteins; repairs damage due to oxidative stress, and is involved in photosynthesis, DNA repair, and apoptosis.

Vitamin B₃ (niacin, nicotinic acid)
Forms part of the coenzyme NAD⁺ (nicotinamide adenine dinucleotide); involved in DNA repair and the production of steroid hormones in the adrenal gland.

Vitamin B₅ (pantothenic acid)
Required for the synthesis of coenzyme-A; needed in the synthesis and metabolism of proteins, carbohydrates, and fats.

Vitamin B₆ (pyridoxine, pyridoxal phosphate)
A cofactor in many reactions in amino acid metabolism; necessary for the enzymatic reaction governing the release of glucose from glycogen.

Vitamin B₇ (biotin)
A coenzyme in the metabolism of fatty acids and some amino acids, and plays a role in gluconeogenesis.

Vitamin B₉ (folic acid)
A cofactor in methyl group transfers; needed to synthesize and repair DNA; also important in aiding rapid cell division and growth, and producing healthy red blood cells (and preventing anemia).
**Water-Soluble Vitamins**

**Vitamin B₁₂ (cobalamin)**
A coenzyme in amino acid metabolism; important in normal functioning of the brain and nervous system, and in the production of blood; involved in the synthesis of DNA and fatty acids. The cyanocobalamin form is often used in B₁₂ supplements because it is easier to purify after bacterial fermentation.

**Vitamin C (ascorbic acid)**
Acts as an antioxidant; cofactor in at least eight enzymatic reactions; involved in the synthesis of collagen (prevention of scurvy).
**Fat-Soluble Vitamins**

Vitamin A (retinol, retinal)
- Involved in the synthesis of visual pigments, and acts as a growth factor for epithelial cells.
- Vitamin A can be produced from four carotenoid pigments: beta, alpha, and gamma carotene, and from beta-cryptoxanthin.

![Chemical structures of vitamin A precursors](image)

**Fat-Soluble Vitamins**

Vitamin D₂ (ergocalciferol)
- Produced from ergosterol by the action of UV light

Vitamin D₃ (cholecalciferol)
- Produced from 7-dehydrocholesterol by the action of UV light

![Chemical structures of vitamin D precursors](image)
**Fat-Soluble Vitamins**

*Vitamin E (α-tocopherol)*

α-tocopherol is the most biologically active form of Vitamin E (wheat germ oil, sunflower oil, safflower oil)

*Vitamin E (γ-tocopherol)*

γ-tocopherol is the most common form of Vitamin E in the North American diet (corn oil, soybean oil, margarine, dressings)

---

**Fat-Soluble Vitamins**

*Vitamin K₁ (phylloquinone)*

Found in green leafy vegetables, soybean oil

*Vitamin K₂ (menaquinone)*

Produced by bacteria in the small intestine
Minerals

• **Minerals** are metals or nonmetals used in the body in the form of ions or compounds. Although we talk about them as if they are in their pure elemental form, all of these substances are ingested in the form of either ionic or molecular compounds.

  – **Major minerals** are found in the body in quantities greater than 5 grams.
    • They are inorganic structural components of bones and teeth (Ca, P), or are needed in large amounts for the regulation of fluids and the transmission of nerve impulses (Na, K).
  – **Trace minerals** are found in the body in smaller amounts.
    • They are components of vitamins, enzymes, hormones, or specialized proteins.

Chapter 12 Nutrition and Energy for Life
Metabolism and an Overview of Energy Production

The Sun and Photosynthesis

- The sun is the ultimate source of energy for all biological processes. This energy results from the fusion of hydrogen atoms to form helium atoms:

\[
4H \xrightarrow{\text{nuclear fusion}} \text{He} + \text{energy}
\]

- A portion of this energy reaches the Earth’s surface as sunlight, and is captured by the chlorophyll in plants. This energy drives the conversion of carbon dioxide and water to form glucose, and then into starch, triglycerides, and other forms of stored energy:

\[
6\text{CO}_2 + 6\text{H}_2\text{O} + \text{energy} \xrightarrow{\text{photosynthesis}} \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2
\]

- All animals obtain energy either directly or indirectly from these energy stores in plants.
Cellular Respiration

- During cellular respiration, plants and animals combine energy-rich compounds with oxygen from the air, producing CO₂ and releasing energy.
- Cellular respiration can be represented as:

\[
\text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2 \xrightarrow{\text{respiration}} 6\text{CO}_2 + 6\text{H}_2\text{O} + \text{energy}
\]

- A portion of the energy released during respiration is captured in the form of adenosine triphosphate (ATP), which stores energy for use in other processes.
- The remainder of the energy from respiration is released as heat.

Energy Flow in the Biosphere
**Metabolism**

- **Metabolism** is the sum of all reactions occurring in an organism:
  - **catabolism** — the reactions involved in the **breakdown** of biomolecules.
  - **anabolism** — the reactions involved in the **synthesis** of biomolecules.
  - In general, energy is released during catabolism and required during anabolism.

**Metabolic Pathways**

- **A metabolic pathway** is a sequence of reactions used to produce one product or accomplish one process.
  - Each pathway consists of a series of chemical reactions that convert a starting material into an end product (e.g., the citric acid cycle and the electron transport chain).
  - Fortunately, there are a great many similarities among the major metabolic pathways in all life forms.
The Catabolism of Food

The catabolism of food is a three stage process.

- **Stage I:** The digestion of large, complex molecules into simpler ones.
  - The most common reaction in digestion is hydrolysis:

  \[
  \text{proteins} \xrightarrow{\text{hydrolysis}} \text{amino acids}
  \]

  \[
  \text{disaccharides and polysaccharides} \xrightarrow{\text{hydrolysis}} \text{monosaccharides}
  \]

  \[
  \text{fats and oils} \xrightarrow{\text{hydrolysis}} \text{fatty acids + glycerol}
  \]

- **Stage II:** The small molecules from digestion are broken down into even simpler units, usually the two-carbon acetyl portion of acetyl coenzyme A (acetyl CoA):

  \[
  \text{acetyl coenzyme A}
  \]

  - Some energy is produced at this stage, but much more is produced during the oxidation of the acetyl units in Stage III.
The Catabolism of Food

• **Stage III**: This is referred to as the **common catabolic pathway** because the reactions are the same regardless of the type of food being degraded.
  – citric acid cycle
  – electron transport
  – oxidative phosphorylation

• Energy released in Stage III appears in the form of energy-rich molecules of **ATP**.
  – The whole purpose of the catabolic pathway is to convert the chemical energy in foods into molecules of ATP, which carries energy to parts of the cell where energy is needed.

  – *The common catabolic pathway and the ways in which carbohydrates, lipids, and proteins provide molecules that are degraded by this pathway will be discussed in Chapters 13-15.*
ATP: The Primary Energy Carrier

The Structure of ATP

- **Adenosine triphosphate**, ATP, consists of:
  - the heterocyclic base **adenine**
  - the sugar **ribose**
  - a **triphosphate group**

- At physiological pH, the protons on the triphosphate group are removed, giving ATP a charge of -4.
  - In the cell, it is complexed with Mg$^{2+}$ in a 1:1 ratio, giving it a net charge of -2.
The Hydrolysis of ATP

• The triphosphate group is the part of the molecule that is important in the transfer of biochemical energy. The key reaction is the transfer of a phosphoryl group, $-\text{PO}_3^{2-}$, from ATP to another molecule.

  – During the hydrolysis of ATP in water, a phosphoryl group is transferred from ATP to a water molecule:

    \[
    \text{adenosine} - O - P - O - P - O^- + H - OH \rightarrow \text{adenosine} - O - P - O^- + \text{OH} - P - O^- + H^+
    \]

    \[
    \text{ATP} \quad \text{ADP} \quad \text{inorganic phosphate (P)}
    \]

  – The products are adenosine diphosphate (ADP) and a phosphate ion, often referred to as an inorganic phosphate, $P_i$, or just phosphate.

The Hydrolysis of ATP

• The transfer of a phosphoryl group from ATP to water is accompanied by a release of energy.

• Free energy, $\Delta G$, is used as a measure of the energy change.

  – When energy is released, $\Delta G$ is negative.
  – When energy is absorbed, $\Delta G$ is positive.
  – When $\Delta G$ is measured under standard conditions, it is represented by $\Delta G^\circ$.
  – When $\Delta G^\circ$ is measured under body conditions, it is represented by $\Delta G^\circ\prime$. 
The Hydrolysis of ATP

- The liberated free energy is available for use by the cell to carry out processes requiring an input of energy:
  \[ \text{ATP} + \text{H}_2\text{O} \rightarrow \text{ADP} + \text{P}_i + \text{H}^+, \Delta G^{\circ'} = -7.3 \text{ kcal/mol} \]
- Other phosphate-containing compounds also liberate energy on hydrolysis:

<table>
<thead>
<tr>
<th>Reaction</th>
<th>Free Energy Change (kcal/mol)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phosphoenolpyruvate + H_2O → pyruvate + phosphate</td>
<td>-14.8</td>
</tr>
<tr>
<td>Carbamoyl phosphate + H_2O → ammonia + CO_2 + phosphate</td>
<td>-12.3</td>
</tr>
<tr>
<td>1,3-bisphosphoglycerate + H_2O → 3-phosphoglycerate + phosphate</td>
<td>-11.8</td>
</tr>
<tr>
<td>Phosphocreatine + H_2O → creatine + phosphate</td>

<td>-3.3</td>
</tr>
<tr>
<td>Glycerol-3-phosphate + H_2O → glycerol + phosphate</td>
<td>-2.2</td>
</tr>
</tbody>
</table>

The Hydrolysis of ATP

- Compounds that liberate a large amount of free energy on hydrolysis are called high-energy compounds.
- The hydrolysis of ATP to ADP is the principal energy-releasing reaction for ATP. Some other hydrolysis reactions occur under some conditions, such as the hydrolysis of ATP to adenosine monophosphate, AMP, and pyrophosphate, PP_i:

\[ \text{ATP} + \text{H}_2\text{O} \rightarrow \text{AMP} + \text{PP}_i + 2\text{H}^+, \Delta G^{\circ'} = -8.0 \text{ kcal/mol} \]
Chapter 12 Nutrition and Energy for Life

**The Hydrolysis of ATP**

- This is usually followed by immediate hydrolysis of the pyrophosphate, which releases even more energy:

$$\text{PP}_i + H_2O \rightarrow 2\text{P}_i + \Delta G^{\circ} = -6.5 \text{ kcal/mol}$$

- The hydrolyses of ATP and related compounds are summarized below:

<table>
<thead>
<tr>
<th>Reaction</th>
<th>$\Delta G^{\circ}$ (kcal/mol)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATP + H$_2$O $\rightarrow$ ADP + P$_i$ + H$^+$</td>
<td>$-7.3$</td>
</tr>
<tr>
<td>ATP + H$_2$O $\rightarrow$ AMP + PP$_i$ + 2H$^+$</td>
<td>$-8.0$</td>
</tr>
<tr>
<td>PP$_i$ + H$_2$O $\rightarrow$ 2P$_i$</td>
<td>$-6.5$</td>
</tr>
<tr>
<td>ADP + H$_2$O $\rightarrow$ AMP + P$_i$ + H$^+$</td>
<td>$-7.3$</td>
</tr>
</tbody>
</table>

**The ATP-ADP Cycle**

- ATP functions as an immediate donor of free energy rather than as an energy storage medium.
  - The turnover rate of ATP is very high: typically, an ATP molecule is hydrolyzed within 1 minute after its formation.
  - At rest, a human body hydrolyzes ATP at the rate of about 40 kg every 24 hours.
  - During strenuous exertion, this rate may be as high as 0.5 kg per minute.

- ATP must be continuously regenerated from ADP if cellular work is to occur.
**Mitochondria**

- The **mitochondrion** is the powerhouse of the cell. It is the organelle where many of the reactions of the common catabolic pathway occur. It consists of an outer membrane, which surrounds a inner membrane.
  - The folds of the inner membrane are called **cristae**.
  - The space that surrounds them is the **matrix**.
- The enzymes for ATP synthesis (electron transport and oxidative phosphorylation) are located on the cristae. The enzymes for the citric acid cycle are found within the matrix, near the surface of the inner membrane.

**An Animal Cell**

Schematic of typical animal cell:
1. Nucleolus
2. Nucleus
3. Ribosomes
4. Vesicle
5. Rough endoplasmic reticulum (ER)
6. Golgi body
7. Cytoskeleton
8. Smooth ER
9. Mitochondria
10. Vacuole
11. Cytosol
12. Lysosome
13. Centrioles within centrosome
Important Coenzymes in the Common Catabolic Pathway

**Coenzyme A**

- Coenzymes are weakly-bound organic groups that participate in enzyme-catalyzed reactions, often by acting as shuttle systems for the transfer of chemical groups (e.g., hydrogen transport). Many important coenzymes are formed from vitamins.

- Coenzyme A is a central compound in metabolism. It is part of acetyl coenzyme A (acetyl CoA), the substance formed from all foods as they pass through Stage II of catabolism.
Coenzyme A

• Components of coenzyme A:
  – vitamin B₅, pantothenic acid, in the center.
  – a phosphate derivative of ADP
  – β-mercaptoethylamine, which puts a reactive sulfhydryl group (—SH) at the end of the molecule (CoA—SH).

Coenzyme A

• The letter A is included in the name Coenzyme A to signify its participation in the transfer of acetyl groups, but Coenzyme A transfers all acyl groups. This is important in fatty acid oxidation and synthesis.

• Acyl groups are linked to coenzyme A through the sulfur atom in a thioester bond:

\[
\begin{align*}
\text{CH}_3 - & C - \overset{\delta}{\text{O}} \\
\text{acyl group} & \\

\text{R} - & C - \overset{\delta}{\text{O}} \\
\text{acyl group} &
\end{align*}
\]
Electron Transporters

- Most of energy for ATP synthesis is released when the oxygen we breathe is reduced.
  - Oxygen accepts electrons and $H^+$, producing water.
  - The electrons come from the oxidation of fuel molecules, but are not transferred directly to the oxygen.
  - These substrates first transfer the electrons to special coenzyme carriers.
    - The reduced forms of these coenzymes transfer the electrons to oxygen through the reactions of the electron transport chain.
    - ATP is formed from ADP and $P_i$ as a result of this flow of electrons.

Nicotinamide Adenine Dinucleotide ($NAD^+$)

- Nicotinamide adenine dinucleotide ($NAD^+$), is an electron transporter which is a derivative of ADP and the vitamin nicotinamide ($B_3$).
**Nicotinamide Adenine Dinucleotide (NAD\(^+\))**

- The reactive site of NAD\(^+\) is in the nicotinamide portion.
  - When oxidizing a substrate, the nicotinamide ring accepts two electrons and one proton, forming the reduced coenzyme NADH:

  ![Nicotinamide Adenine Dinucleotide (NAD\(^+\))](image)

- A typical cellular reaction in which NAD\(^+\) serves as an electron acceptor is the oxidation of an alcohol:

  ![Nicotinamide Adenine Dinucleotide (NAD\(^+\))](image)

  - In this reaction, one hydrogen atom of the alcohol substrate is directly transferred to NAD\(^+\), whereas the other appears in solution as H\(^+\). Both electrons lost by the alcohol have been transferred to the nicotinamide ring in NADH.
Nicotinamide Adenine Dinucleotide (NAD$^+$)

- Biochemical reactions involving coenzymes are often written more concisely:

![Chemical reaction diagram]

- This notation emphasizes the oxidation reaction and the involvement of the coenzyme.

Example: Biochemical Reactions

- Write the following reaction in the normal form of a chemical equation:

![Chemical reaction diagram]
**Flavin Adenine Dinucleotide (FAD)**

- Flavin adenine dinucleotide (FAD) is another major electron carrier. It is a derivative of ADP and the vitamin riboflavin.

![Flavin Adenine Dinucleotide (FAD) structure](image)

**Flavin Adenine Dinucleotide (FAD)**

- The active site is located within the riboflavin ring system. Unlike NAD\(^+\), FAD accepts both of the hydrogen atoms lost by the substrate, forming the reduced species FADH\(_2\):

![Flavin Adenine Dinucleotide (FAD) reaction](image)
Flavin Adenine Dinucleotide (FAD)

- The substrates for reactions involving FAD are often those in which a \(-\text{CH}_2\text{CH}_2-\) portion of the substrate is oxidized to a double bond:

\[
\begin{align*}
\text{H} & \quad \text{H} \\
R-C-C-R + \text{FAD} & \rightarrow R-\text{CH}═\text{CH}-R + \text{FADH}_2 \\
\text{unsaturated} & \quad \text{(oxidized)} \\
\text{H} & \quad \text{H} \\
saturated & \quad \text{(reduced)}
\end{align*}
\]

Specific example:

\[
\begin{align*}
\text{CH}_3\text{CH}_2\text{CH}_2 - C - \text{S} - \text{CoA} & \quad \text{CH}_3\text{CH}═\text{CH} - C - \text{S-CoA} \\
\text{butyryl CoA} & \quad \text{FAD} \\
\text{FADH}_2
\end{align*}
\]

Example: Biochemical Reactions

- Complete the following reactions:

\[
\begin{align*}
\text{OOC-CH}_2\text{-CH}_2\text{-COO}^- + \text{FAD} & \rightarrow \\
\text{OH} & \quad \text{CH}_3\text{-CH-}-\text{COO}^- + \text{NAD}^+
\end{align*}
\]
